<b>6.2. Slicing Strings</b> .....	3
<b>6.3. Modifying Strings</b> .....	3
<b>6.4. Escape Characters</b> .....	4
<b>6.5. String Methods</b> .....	5
<b>Lesson 6: Review Questions</b> .....	6

### 6.1. Declaration

Strings in python are surrounded by either single quotation marks, or double quotation marks.

'hello' is the same as "hello".

You can display a string literal with the `print()` function:

#### Example

```
print("Hello")  
print('Hello')
```

Assigning a string to a variable is done with the variable name followed by an equal sign and the string:

#### Example

```
a = "Hello"  
print(a)
```

You can assign a multiline string to a variable by using three quotes:

#### Example

You can use three double quotes:

```
a = """Lorem ipsum dolor sit amet, consectetur adipiscing elit, sed do eiusmod tempor  
incididunt labore et dolore magna aliqua."""  
print(a)
```

Or three single quotes:

```
a = 'Lorem ipsum dolor sit amet, consectetur adipiscing elit, sed do eiusmod tempor  
incididunt ut labore et dolore magna aliqua.'  
print(a)
```

To get the length of a string, use the `len()` function.

To check if a certain phrase or character is present in a string, we can use the keyword `in`.

#### Example

Check if "free" is present in the following text:

```
txt = "The best things in life are free!"  
print("free" in txt)
```

To check if a certain phrase or character is NOT present in a string, we can use the keyword `not in`.

#### Example

Check if "expensive" is NOT present in the following text:

```
txt = "The best things in life are free!"  
print("expensive" not in txt)
```

## 6.2. Slicing Strings

You can return a range of characters by using the slice syntax.

Specify the start index and the end index, separated by a colon, to return a part of the string.

### Example

Get the characters from position 2 to position 5 (not included):

```
b = "Hello, World!"  
print(b[2:5])
```

Note: The first character has index 0.

By leaving out the start index, the range will start at the first character:

### Example

Get the characters from the start to position 5 (not included):

```
b = "Hello, World!"  
print(b[:5])
```

By leaving out the *end* index, the range will go to the end:

### Example

Get the characters from position 2, and all the way to the end:

```
b = "Hello, World!"  
print(b[2:])
```

Use negative indexes to start the slice from the end of the string:

### Example

Get the characters:

```
From: "o" in "World!" (position -5)  
To, but not included: "d" in "World!" (position -2):  
b = "Hello, World!"  
print(b[-5:-2])
```

## 6.3. Modifying Strings

Python has a set of built-in methods that you can use on strings.

### Upper Case:

The `upper()` method returns the string in upper case:

```
a = "Hello, World!"  
print(a.upper())
```

### Lower Case:

The `lower()` method returns the string in lower case:

```
a = "Hello, World!"  
print(a.lower())
```

### Remove Whitespace

Whitespace is the space before and/or after the actual text, and very often you want to remove this space.

The `strip()` method removes any whitespace from the beginning or the end:

```
a = " Hello, World! "  
print(a.strip()) # returns "Hello, World!"
```

## Replace String

The `replace()` method replaces a string with another string:

```
a = "Hello, World!"  
print(a.replace("H", "J"))
```

## Split String

The `split()` method returns a list where the text between the specified separator becomes the list items.

The `split()` method splits the string into substrings if it finds instances of the separator:

```
a = "Hello, World!"  
print(a.split(",")) # returns ['Hello', ' World!']
```

## 6.4. Escape Characters

To insert characters that are illegal in a string, use an escape character.

An escape character is a backslash `\` followed by the character you want to insert.

An example of an illegal character is a double quote inside a string that is surrounded by double quotes:

### Example

You will get an error if you use double quotes inside a string that is surrounded by double quotes:

```
txt = "We are the so-called \"Vikings\" from the north."
```

To fix this problem, use the escape character `\`:

The escape character allows you to use double quotes when you normally would not be allowed:

```
txt = "We are the so-called \"Vikings\" from the north."
```

Other escape characters used in Python are:

Code	Result
<code>\'</code>	Single Quote
<code>\\</code>	Backslash
<code>\n</code>	New Line
<code>\r</code>	Carriage Return
<code>\t</code>	Tab
<code>\b</code>	Backspace
<code>\f</code>	Form Feed
<code>\ooo</code>	Octal value
<code>\xhh</code>	Hex value

## 6.5. String Methods

Python has a set of built-in methods that you can use on strings. Some of them are:

Method	Description
<a href="#"><code>capitalize()</code></a>	Converts the first character to upper case
<a href="#"><code>casefold()</code></a>	Converts string into lower case
<a href="#"><code>center()</code></a>	Returns a centered string
<a href="#"><code>count()</code></a>	Returns the number of times a specified value occurs in a string
<a href="#"><code>encode()</code></a>	Returns an encoded version of the string
<a href="#"><code>endswith()</code></a>	Returns true if the string ends with the specified value
<a href="#"><code>expandtabs()</code></a>	Sets the tab size of the string
<a href="#"><code>find()</code></a>	Searches the string for a specified value and returns the position of where it was found
<a href="#"><code>format()</code></a>	Formats specified values in a string
<code>format_map()</code>	Formats specified values in a string
<a href="#"><code>index()</code></a>	Searches the string for a specified value and returns the position of where it was found
<a href="#"><code>isalnum()</code></a>	Returns True if all characters in the string are alphanumeric
<a href="#"><code>isalpha()</code></a>	Returns True if all characters in the string are in the alphabet
<a href="#"><code>isdecimal()</code></a>	Returns True if all characters in the string are decimals
<a href="#"><code>isdigit()</code></a>	Returns True if all characters in the string are digits
<a href="#"><code>isidentifier()</code></a>	Returns True if the string is an identifier
<a href="#"><code>islower()</code></a>	Returns True if all characters in the string are lower case
<a href="#"><code>isnumeric()</code></a>	Returns True if all characters in the string are numeric
<a href="#"><code>isprintable()</code></a>	Returns True if all characters in the string are printable
<a href="#"><code>isspace()</code></a>	Returns True if all characters in the string are whitespaces
<a href="#"><code>istitle()</code></a>	Returns True if the string follows the rules of a title

**Lesson 6: Review Questions**

1. Write a program that demonstrates various string methods.
2. Explain scenarios where you would use string instead of an array of characters.
